10 Vision Statement

11 Context and Drivers (Factors, PEST analysis, Reference to other international agreements)

12 Long Term Ambitions

13 Guiding Principles (from Task Team document)

14 Conditions for Success (from Task Team document)

15
16 **PART II: Action Plan (2020 to 2030)**

17 Purpose

18 Outcomes, Outputs, and Activities by Ambition

- 19 • Specific roles and responsibilities
- 20 • Deliverables, resources required, timeline, and metrics for success.

21 Partnerships (from Task Team document)

22
23 **ANNEX**

24 (CG-18 and EC-71 Resolutions Text, and text concerning WMO Strategic Plan)

- 25 • Formation of the Hydrological Assembly
- 26 • Formation of the Hydrological Coordination Panel
- 27 • Mandate for the Vision and Strategy for Hydrology and Associated Plan of Action,
28 Including Major Hydrological Initiatives (Pillars)
- 29 • Relationship to the WMO Strategic Plan
- 30 • Congress-Approved Reference to Other International Agreements
- 31 • Definition of Operational Hydrology

32

PART II: Action Plan

1) Purpose

WMO Members states/National Hydrologic Services/NHMS/UN organizations responsible for other Water programs will collaborate under this Action Plan to implement a strategic suite of enhanced services for operational hydrology to be supported by the WMO by 2030, to achieve the Long-Term Ambitions, thus significantly improving capacity of National Hydrologic Services to deliver enhanced products and services based on cutting edge science and technology.

2) Outputs and Activities by Ambition

The Eighteenth WMO Congress in 2019 approved eight long-term ambitions that should guide the development of WMO activities relevant to water. Each ambition represents a goal that society aims to achieve in the frameworks of sustainable development and disaster risk management. Following section presents major outcomes necessary to reach each of ambition and lists all identified contributing outputs.

53 **2.1 Cross-cutting issues**

54
55
56
57
58
59
60

Little will be done, if the National Hydrological Service is not fully responding to its goals and objectives due to lack of finance, lack of professional staff, insufficient equipment, and more.

Michael Maehaka, consultation on needs and gaps

61 Gaps identification and consultations made during preparation of this Action Plan revealed
62 that some issues are of clearly cross-cutting nature and are prerequisites to achieve any of
63 eight long-term ambitions. These are related mainly to functioning of National Hydrological
64 Services, including its visibility, financing, sustainability, governance and management.
65 Unfortunately, in some parts of the World, responsible services struggle to maintain long-
66 term monitoring due to limited financial resources leading to patchy (or no) data.

67 There is a need to extend the outputs and activities to enhance visibility of the NHSs with
68 respective governments to ensure recognition and sustainability (adequacy) of budget
69 allocations for hydrological services. At the same time, sustainability of operations
70 (including monitoring networks, capacity building, personnel stability and training) was
71 identified as a clear prerequisite for any operation and service delivery.

72 Hand in hand with political recognition comes also data policy set-up. Monitoring,
73 observation and data sharing has been identified as a critical component of NMHSs
74 operations that needs to be enhanced to aim deliver majority of outcomes identified bellow.
75 Downstream and upstream countries in a transboundary basin are in an asymmetric
76 position with respect to data exchange, with downstream countries requiring hydrologic
77 data as well as forecasting products from the upstream countries. On top of that,
78 hydrological/water resources data are sometimes considered to be strategic information and
79 possible subject of international disputes over water impacts. In such a case, the decision
80 on data policy is not at National Hydrological Service level, but at governmental level.

81 Besides policy issues, technical (easy to use and maintain) capability to effectively exchange
82 data might be limiting factor in international data sharing (communication links, servers,
83 protocols implemented).

84 At the same time, involvement of hydrological community remained limited in particular to
85 integrated programmes and activities of the WMO like WIS/WIGOS, GDPS etc.

86
87 Therefore, following outcomes were proposed to support all 8 long-term ambitions.
88

89 **Outcomes:**

- 90 1) National Hydrological Services operations are sustainable, visible for the society
91 and governments, and benefits provided are recognized and valued.
92 2) Financing schemes of hydrological services are improved to ensure sustainability of
93 operation and attractiveness for professional staff.
94 3) Increased sharing of hydro-meteorological data for operational hydrology on free and
95 unrestricted basis across political border
96 4) Increased involvement of hydrological communities of Members in global activities of
97 the WMO and enhanced benefits transfer to national scale services
98

- 99 **Metrics:** Success in this outcome will be measured by:
100 1) Number of Members reporting through Country Profile Database sustainable financial
101 (budgeting) situation
102 2) Number of station registered by Members to reference hydrological network and
103 sharing data
104 3) Number of Members providing operational and historical data from WHOS (phase II)
105 system
106 4) Number of experts registered to expert database with hydrology specialization,
107 5) Number of experts with hydrology expertize involved in working structures of
108 technical commissions and regional associations.
109

110 **Outputs:**

111 *A.1 Increased presentation/ communication understanding of value proposition, benefits*
112 *and, risk analysis and value of hydrological services to foster understanding by*
113 *ministries and governments*
114

115 Hydrological Assembly presents an opportunity for representatives of hydrological
116 community to participate actively in strategic work of the organization. NMHSs will be
117 supported to engage with politicians and better describe values of NMHSs by organizing
118 Regional Associations High Level Fora, leader's coalition and by provision of communication
119 materials and toolkits.
120

121 *A2 Enhanced regional cooperation, planning and implementation of NMHSs led activities*
122

123 Regional Associations hydrological activities (e.g. HydroConference in RAVI) and support to
124 other technical symposia will be organized to coordinate on regional hydrological
125 requirements.
126

127 *A3 Increased management skills of NHSs management (including middle and lower*
128 *management) supports effectiveness and development of NHSs*
129

130 Capacity building activities for top and middle management of NMHSs will be prepared
131 including guidelines development, training courses, targeted twinning projects and
132 promotion activities.
133

134 *A.4 Enhanced customer orientation and better marketing skills generates better services*
135 *and products with higher added value*
136

137 Targeting customer orientation skills of the NMHSs by training materials and case studies
138 will help to establish better services, build tighter connections with and increase satisfaction
139 of users of products and services.
140

141 *A.5 The end-users of hydrological information/data have a clear understanding of what the*
142 *data means and it's relative (un)certainity.*
143

144 Developing of unified communication standards for hydrological information based on
145 definition of guidelines and regulatory material to ensure that communication is based on
146 uptake requirements defined by end-users.

147
148 *A.6 Institution development plans and programmes of monitoring network development are*
149 *in place and implemented taking into account the catalogue of products and services*
150

151 Planning of development and operation helps to achieve sustainability of observations and
152 services provided by the NMHSs. NHS providers have the tools to plan and construct
153 hydrological networks that can grow/adapt as needs and resources changes delivered by
154 targeted research. Guidelines on hydrological monitoring network design, implementation
155 and maintenance are available.

156
157 *A.7 Enhanced resource mobilization (expertise, financial, partnership) for capacity building,*
158 *technical assistance, training of personnel and sustainability of E2E MHEWS and*
159 *drought management*
160

161 Project proposals development support by a framework mechanism to sponsor development
162 initiatives through Project Proposal development and provision of Reimbursable Advisory
163 Services through e.g. the IFM HelpDesk, IDMP, Regional offices and in cooperation with
164 other partners.

165
166 *A.8 Sustainable projects helps build capacities of NHSs*
167

168 Capacity development projects in monitoring and data assessment are coordinated across
169 UN bodies and build to support achievement of 8 long term ambitions. Sustainability aspect
170 of the projects is supported by SOFF, use of local resources to maintain equipment, and by
171 standardization & use of open platforms.

172
173 *A.9 Effective and efficient, low-cost methods for hydrological observations are broadly*
174 *available*
175

176 Guidance will be developed on how to amplify the information through citizen science, proxy
177 data, and innovation. HydroHub Innovation hub will stimulate development and deployment
178 of low-cost technologies for hydrometric monitoring.

179
180 *A.10 Increased availability, national and international exchange of hydro-meteorological*
181 *data for operational flood forecasting and early warning, and enhanced international*
182 *cooperation in flood management especially for transboundary basins*
183

184 To support Resolution 42 and its implementation a network of reference observations is
185 established from which Members commit themselves to mandatory share the data leading
186 to future inclusion of hydrology and cryosphere data to GBON. WHOS will be further
187 implemented for sharing of operational and historical data among Members including
188 demonstration projects on additional types of data (e.g. forecast products from various
189 producers).

190
191 *A.11 Operational hydrology community at national scale knows how to access the global*
192 *products, services, tools, activities and community of WMO*

193
194 Overcoming the input obstacles for hydrologists to WMO activities will be done by
195 developing an 'accueil' directory and will be supported by explanation of benefits for NHSs
196 to become active part of the WMO family.

197
198 **On-going activities**

199 Given the cross-cutting nature of above listed outputs for enhancement of sustainability of
200 National Hydrological Services and increased data sharing, many of on-going hydrological
201 activities need to be continued and intensified to achieve long term ambitions. **Capacity**
202 **building in hydrology and water management** and capacity development through
203 projects supported by **APFM** and **IDMP** programmes will be critical for succeed. Governance
204 of National Hydrological Services and its effective operation to deliver high value users'
205 oriented products and services needs to be framed in principles of **Quality management**
206 **framework – Hydrology**. At the same time, development of observation networks and
207 data sharing demands for continuing advancement of **Hydrological data operation and**
208 **management** through implementation of **WHOS** and intensified use of **The Global**
209 **Hydrometry Support Facility (HydroHub)** to stimulate development of technology and
210 methods of observation and data processing.

211
212 **Assumptions and risks:**

213 We assume that water and hydrometeorological disasters will continue to be considered
214 priority for societal needs both in short term and long term political perspective.

215
216 Risks are in possible:

- 217 • change in overall political and societal priorities e.g. due to COVID-19 pandemic
218 results decrease the involvement of politicians in water-related agenda;
- 219 • lack of alignment with other activities in the field of Water (e.g. UNESCO-IHP)
220 leading to competition for attention of governments;
- 221 • Technological game changer undermines the importance and the role of national
222 services.

223
224 **To be finalized based on consultations**

225

226 **2.2 ambition/goal: No one is surprised by a flood**

227

228

229

230

231

232

Lack of trained people and good hydrological monitoring network is the biggest gap in the process of creating flood forecasting and warning service. Vasko Stojov, consultation on needs and gaps

233

234

235

236

237

238

239

240

Floods represents major hydro-meteorological hazards from the point of view of the number of affected people. While the total economic damage caused by floods has tended to increase, flood early warning systems have proved to be an effective tool to decrease the numbers of fatalities. Increased understanding of flood hazard and risk, flood forecasting and warning have enhanced the preparedness and response capacities of nations and communities. Further strengthening of Members' Early Warning systems for floods is necessary to be prepared for future floods and changes in flood hazard and flood risk.

241

Outcomes:

242

243

244

245

246

247

- Impact based end-to-end early-warning systems (EWS) for flood forecasting in the context of a broader integrated flood management strategy implemented by Members.
- Public, communities and businesses have enhanced access to and better capacity to react to official national hydrological forecasts and warnings globally and locally.

248

Metrics: Success in this outcome will be measured by:

249

250

251

252

253

254

- 1) Number of Members having Multi-hazard Early Warning System set up for floods (at least 80 % of Members declared substantial or comprehensive achievement for all 4 major components of EWS for floods in Sendai Monitor of UNDRR).
- 2) Number of Members providing their flood warnings via GMAS (at least 50 % of Members doing so)

255

Needs and gaps

256

257

258

259

260

261

262

263

Floods are the most important nature disasters and are a result of combination of various phenomena and processes. In consequence, many WMO programs and activities address floods in a certain way, what means a challenge for effective coordination.

Gaps and needs of National flood forecasting and early warning system are not identified in a consistent and organised way. Additionally, there's a lack of expertise to design and development of a flood forecasting and warning system in some regions and low standardization of data flows and methods of operation makes it difficult to transfer solution easily, including language barriers.

264

265

266

267

268

269

270

271

Flood risk assessment process (tools) is not available or not fully understood by all Members. In some countries, collaboration between NHSs, NMSs, and other authorities involved in flood forecasting (National DRR Authorities) towards the creation of Multi-hazard early warning system (MHEWS) is not effective enough. Sometime, processes in flood early warning are understood as sequential steps where components of MHEWS (risk knowledge; monitoring and forecasting; dissemination; capacity to respond) are dealt as completely separate issues without considering the whole value chain. Such discrimination of actions might lead to in-effectivities at interfaces and lack of coordination. A special importance

272 should due to flash floods that demand for different approaches and tools to be used for
273 efficient early warning.

274 Financial resources are limited, both at national and international level to realize all
275 necessary development projects around the World. Additionally, after the investment,
276 lacking resources for operation and maintenance (sustainability) are often a reason for
277 failure, degradation or sub optimal functioning of developed systems.

278 Sharing of data in near-real time remains a challenge in some parts of the World. Use of
279 global coverage products (satellite, NWP, hydro models), despite its huge development over
280 last few decades, remains limited in operational hydrology (likely due to data policy, IT
281 connection, lack of knowing where to search, etc.). When using global products,
282 quantitative interpretation is often needed, but access to basic data (of hydrological
283 meaning) at reasonable scale is rarely available. Experience also shows that majority of
284 Members have some gaps in conveying forecast and warning information to users, which
285 results in decrease of effectiveness of forecasts and warnings.

286 In a wider scope, a flood protection sometimes neglects Integrated flood risk management
287 principles. Considering development of end-to-end early warning system without a context
288 of other components of flood protection (land-use planning, reservoir operation, response
289 planning etc.) leads to conflicts and inefficiency where holistic approach is not applied.

290

291 **Outputs:**

292 *B.1 Enhanced coordination, effectiveness and governance of all WMO activities in supporting*
293 *Members in Flood Risk Assessment and Flood Forecasting and Warning*

294

295 Flood Forecasting Initiative will be reinforced as coordination mechanisms of activities for
296 Flood Risk Assessment, Forecasting and Warning across WMO. Effective joint planning and
297 implementation mechanisms must be initiated with major partners and activities (e.g. IFI,
298 UNDRR), similarly WMO will seek for principles of cooperation with private sector in this
299 issue.

300

301 *B.2 Framework is developed for evaluation of gaps and needs of National flood forecasting*
302 *and early warning systems*

303

304 Assessment Guidelines will be developed, completed by community supported web
305 based tool for self-evaluation.

306

307 *B.3 Increased exchange of knowledge and technical expertise in flood forecasting among*
308 *Members*

309

310 Knowledge transfer will be realized through Community of Practice on End-to-End Early
311 Warning Systems for Flood Forecasting, including guidance on emerging technologies
312 and services for data acquisition and analysis.

313

314 *B.4 Enhanced collaboration among NHSSs, NMSs and other organizations (e.g. DRR*
315 *authorities) at national level in developing and operating E2E MHEWS particularly*
316 *including floods*

317

318 Support will be provided for inclusion of different stakeholders' requirements (energy-water-
319 food) by compilation of success stories for collaboration among NMHSs and DRR authorities.
320 Promotion of MHEWS approach (e.g. with the integration of FFGS/CIFI/SWFP) for
321 integration of hydrology in GMAS (including humanitarian support and reflecting
322 hydrological hazards in the catalogue of hazardous events) by explaining concept of EWS
323 and showcasing benefits of coproduction of MHEWS services between communities.
324

325 *B.5 Increased availability and international exchange of hydro-meteorological data for*
326 *operational flood forecasting and early warning, and enhanced international*
327 *cooperation in flood management especially for transboundary basins on free and*
328 *unrestricted basis.*

329
330 See A.10

331
332 *B.6 Enhanced resource mobilization (expertise, financial, partnership) for capacity building,*
333 *technical assistance, training of personnel and sustainability of E2E MHEWS*
334

335 See A.7 (Project proposal development will be supported by a framework mechanism to
336 sponsor development initiatives through Project Proposal development and provision of
337 Reimbursable Advisory Services through the IFM HelpDesk.)
338

339 *B.7 Flood related data and products with global and regional coverage are available for the*
340 *use at national scale by Members*

341
342 Establish RSMC centers with function in the field of operation flood forecasting within GDPFS
343 to support Members with global and regional product and verification. Develop inventory of
344 world- wide and regional free and public data and products for Flood forecasting; and
345 inventory of international interoperable models and platforms.
346

347 *B.8 Increased Members' capacities to communicate to the public and raising the awareness*
348

349 Set of guidelines, best practices and training materials will be prepared including CAP
350 application to hydrological hazards, communication of uncertainty, impact based
351 forecasting, and communication with users on their requirements as well as on
352 interpretation of forecasting results and related risks.
353

354 *B.9 Increased Members' and Regions' (basins) application of integrated flood risk*
355 *management principles in flood prevention, preparedness and response.*
356

357 Continuing APFM activities in capacity building in integrated flood management
358

359 **On-going activities**

360 The **WMO FFI Flood Forecasting Initiative** and **APFM** has been the major contributions
361 to flood related disaster risk management activities that need to continue and further
362 develop in order to achieve long-term ambition 'no one is surprised by a flood'. Relevant
363 activities needs a continuing support by **Capacity building in hydrology and water**

364 **management**, which helped increase capacities of Members in flood risk assessment and
365 flood forecasting and warning in previous years. However, reliable flood forecasting service
366 can be built only if **Hydrological data operation and management** provides sufficient
367 (amount, quality, resolution) data and **Quality management framework – Hydrology**
368 properly address users’ requirements and helps establish and maintain processes to deliver
369 products and services

370
371 **Assumptions and risks:**

372 We assume that water and hydrometeorological disasters will continue to be considered
373 priority for societal needs both in short term and long term political perspective.

374
375 Risks are in possible:

- 376 • Change in overall political and societal priorities e.g. due to COVID-19 pandemic
377 results in decreased involvement in water-related agenda
- 378 • COVID 19 pandemic is altering WMO modalities of work, with a potential impact on
379 efficiency due to teleworking and impossibility of face-to-face meetings.
- 380 • Lack of alignment with other activities in the field of Water (e.g. UNESCO-IHP)
381 leading to competition for attention of governments.
- 382 • Technological game changer undermines the importance and the role of national
383 services in flood forecasting
- 384 • In case of community of practice, also in insufficient contribution from Members and
385 competition of other communities of practices outside WMO for resources (mostly
386 human)
- 387 • In case of GDPFS, lack of candidates to become centers operating under GDPFS rules
388 and development of centers outside the umbrella of GDPFS (including in private
389 sector) that undermines the idea of GDPFS as well as lack of acceptance of the
390 GDPFS hydrology structure by NHSs
- 391 • Lack of financial resources for core activities of the Secretariat

392
393 **To be finalized based on consultations**

394

395 **2.3 ambition/goal: Everyone is prepared for drought**

396

397

398

399

400

I believe, we can start somewhere and we can start simple. Ram Dhurmea, consultation on needs and gaps

401 Although drought can cause water and food shortages, impact the health of the population
402 (including increased morbidity and death), and have socio-economic and political
403 consequences, many drought-affected countries do not yet have national drought policies or
404 existing policies may need to be updated; countries need further assistance in enacting
405 policies that incorporate the three pillars of drought management (monitoring and early
406 warning systems, vulnerability and impact assessments, and mitigation and response
407 measures).

408 Drought is a complex phenomenon connecting meteorological, climatological, hydrological
409 and other communities to support resilience of communities and nations by provision of
410 data and information on drought including precipitation, low-flow, groundwater, soil
411 moisture, lakes and reservoirs, water withdrawal, etc. WMO activities support Members
412 drought preparedness, using (for instance) current capabilities in seasonal to multi-year
413 climate forecasting or drought risk assessment.

414

415 **Outcome:** Members implemented systems for integrated drought management covering
416 drought monitoring and early warning, drought vulnerability and impact assessment &
417 drought mitigation, preparedness and response reduce adverse impacts of drought at all
418 levels.

419 *Alternative wording: Enhanced drought management systems comprising drought
420 Monitoring and Early Warning & drought vulnerability and impact assessment & drought
421 mitigation, preparedness and response implemented by Members*

422

423 **Metrics:** Success in this outcome will be measured by:

- 424 • Number of Members providing their drought preparedness, monitoring and
425 assessment products and services that includes water resources (hydrological)
426 component available through WMO infrastructure (RCOFs, GMAS, HydroSOS)

427

428 **Needs and Gaps**

429 Members sometimes struggle to establish strategy and process to enhance their drought
430 management systems including drought monitoring and assessment. It is usually expected
431 that National Hydrological Service provides products for drought-related decisions on a
432 seasonal scale. But, capacities to run seasonal drought-related forecasts at Members' level
433 are often not available. That includes a fact that it's difficult to reach users to understand
434 their needs and requirements. Successful drought risk assessment needs close cooperation
435 between hazard community (met-hydro) and impact community (agronomy, DRR, etc.),
436 which often lacks functional platform at national scale

437 On top of that, developing drought policies and establishing drought management systems,
438 insufficient amount and quality of data perform drought hazard, vulnerability and risk
439 assessment is an obstacle. Despite substantial progress in remote sensing methods and
440 Earth system modelling, drought related data/estimates from satellites are not well verified
441 on the ground; access to global (satellite and other) products is limited – due to data policy,

442 limited broadband, or lack of know-how. In addition, graphical products are not enough –
443 some consequent quantitative interpretation is often needed, but access to basic data (of
444 hydrological meaning) at reasonable scale is often not available. Similarly, climate
445 (seasonal) forecasts are not always detailed enough (e.g. global products are not easily
446 accessible in quantitative form at useful scale) to be of use for sound hydrological
447 interpretation at national or subnational level. There’s also a challenge in building thrust in
448 seasonal products through demonstration of its benefits for water management.

449
450 When designing and implementing capacity development projects, coordination remains
451 suboptimal in some activities both at national level as well as global level (FAO, WMO,
452 UNESCO) leading to duplication or implementation different tools and systems in one
453 country resulting in obstacles for operation and maintenance. Critical seems to be
454 sustainability of projects after first few years is questionable (investment costs of projects
455 are secured, but financing of maintenance and operation may fail).

456
457 Training of experts in various aspects of drought managements and their support through
458 community of practice and provision of tools and methods remains a challenge for future
459 years.

460
461 **Outputs:**
462 *C.1 Enhanced coordination, effectiveness and governance of all WMO activities in supporting*
463 *Members in Integrated Drought Management*

464
465 Streamlining of ongoing activities on Droughts across the WMO Constituent and Subsidiary
466 bodies will ensure coherence, consistency, and efficient use of resources, building on IDMP
467 continuing Community of Practice and a HelpDesk. Building of partnerships for effective
468 joint planning and implementation mechanisms with major partners and activities (IDI,
469 UNDRR, FAO, IFAD, etc.) as well as with private sector to support drought risk
470 management.

471
472 *C.2 Drought related data and products with global and regional coverage are available for*
473 *the use at national scale by Members*

474
475 Drought related GDPFS centers support NMHSs to process and apply the information to local
476 context. Initiating from identification of requirements from NHSs on globally/regionally
477 produced information for use in drought assessment, modelling and prediction at national
478 scale by NHSs an interface, guidelines and training materials for NHSs will be developed to
479 search, use, interpret and verify products.

480
481 *C.3 Gaps in Members capabilities in drought assessment, monitoring, modelling and*
482 *prediction are known*

483
484 Checklist to enable reviewing current capacities of Member will be developed within the
485 framework for evaluation of gaps and needs of National drought forecasting and early
486 warning systems.

487

488 *C.4 The need of an effective national drought policy is understood by Members*
489
490 Support to Members in developing proactive drought impact mitigation, preventive and
491 planning measures (within the frame of local/national development policies), and risk
492 management, improve the public awareness of drought risk and preparedness for drought.
493

494 *C.5 Increased capacities of Members through training of personnel in drought (low-flow)*
495 *Monitoring, Modelling and Early Warning & drought vulnerability and impact*
496 *assessment & drought adaptation and mitigation, preparedness and response*
497

498 Capacity building activities related to drought management will be organized through the
499 IDMP and regional cooperation, including development of curricula and training material
500 based on Members' needs identification; and support to twinning projects in user driven
501 drought-related products development.
502

503 *C.6 Increased capacities of Members through development projects in the area of*
504 *Monitoring and Early Warning & drought vulnerability and impact assessment &*
505 *drought adaptation and mitigation, preparedness and response*
506

507 See A.6
508

509 *C.7 Increased cooperation (and co-production of services) of hydrological, meteorological*
510 *and climatological communities and international exchange (e.g. higher involvement of*
511 *hydrology in climate outlook forums, basin commissions)*
512

513 Increased co-production of services at regional level through implementation of water
514 segment with RCOFs to provide complete outlooks on climate and water availability to
515 users. Regional Associations produce regular (annual/seasonal/monthly) statements on
516 water resources.
517

518 *C.8 Increased Members capabilities in drought vulnerability and impact assessment of*
519 *different sectors by meaningful drought indicators and indices used at all relevant*
520 *scales.*
521

522 Development of Global Drought Indicator (GDI), including a water scarcity and other
523 hydrological indicators will be supported by development of guidelines on harmonizing
524 drought early warning and risk information for end user communication.
525

526 **Ongoing activities**

527 **Integrated drought management programme (IDMP)** has been developed to support
528 activities in drought/related disaster risk management across WMO domains. Recently,
529 hydrological community has started development of contribution to drought management
530 through designing and promoting the **WMO Global Hydrological Status and Outlook**
531 **System (HydroSOS)**. As for other ambitions, **Capacity building in hydrology and**
532 **water management** and **Quality management framework – Hydrology** traditionally

533 helped in establishing services at Members and basin levels supporting drought
534 management activities.

535

536 **Assumptions and risks:**

537 We assume that integrated drought management is a priority at national level for Members.

538

539 Risks are in possible:

540

- Change in overall political and societal priorities e.g. due to COVID-19 pandemic results in decreased involvement in water-related agenda

541

- COVID 19 pandemic is altering WMO modalities of work, with a potential impact on efficiency due to teleworking and impossibility of face-to-face meetings.

542

- Lack of alignment with other activities in the field of Water (e.g. UNESCO-IHP) leading to competition for attention of governments.

543

544

- In case of GDPFS, lack of candidates to become centers operating under GDPFS rules and development of centers outside the umbrella of GDPFS (including in private sector) that undermines the idea of GDPFS as well as lack of acceptance of the GDPFS hydrology structure by NHSs

545

546

547

548

549

- Lack of financial resources for core activities of the Secretariat

550

551

552

To be finalized based on consultations

553

554 **2.4 ambition/goal: Hydro-climate and meteorological data support the**
555 **food security agenda**

556
557 Resolving the equation of water demand for human consumption, irrigation requirements,
558 water availability and potential water storage needs support as well as providing advice to
559 optimise rain-fed and irrigated agriculture. A multidisciplinary approach, by integrating the
560 agrometeorological, climatological and hydrological expertise with economic and geophysical
561 data and water resources practice, should be developed.

562
563 **Outcomes:**

- 564 1) Food security is enhanced by informed end users' decisions at all levels from regional
565 to local.
566 2) Concept of Integrated water resources management including water use and
567 allocations for supporting food production is widely accepted and followed
568

569 **Metrics:** Success in this outcome will be measured by:

- 570 1) Decreased number of famine/hunger emergencies due to drought and water scarcity
571 (in 2021-2030 relative to 2001-2020).
572 2) Number of members monitoring and accounting for water consumption in their water
573 budgets at basin scale
574

575 **Needs and Gaps**

576 Drought and floods with other hazards were historically the most common causes of food
577 insecurity. While droughts remain at center of focus when speaking about food security,
578 wider understanding to processes and feedbacks within water-food-energy nexus is needed
579 to enable water management support food production in general. Water is understood to be
580 a strategic commodity by some countries and so is water and hydrological data that remains
581 unshared.

582 Successful agrometeorological and climatological products and services were developed in
583 past decades to support rain-fed agriculture, like RCOFs. Hydrological data, products and
584 services need to complement these, in particular, in regions where production depends on
585 irrigation and water allocation schemes depends on water availability and its predictions,
586 concerning both surface and groundwater.

587 Users' needs and requirements are critical substance in developing and delivery of products
588 and services. In this aspect, there's no universal solution, as priorities and preferences of
589 the society are different in different parts of the World. On the other hand, benefits of
590 hydrometeorological services for food production can be easily demonstrated and assessed
591 on yields.

592 At global level, coordination of development projects and cooperation in operational
593 activities needs to be ensured with relevant partners, in particular FAO and WFP
594

595 **Outputs:**

596 *D.1 Increased production and availability of agrometeorological and hydrological forecast*
597 *from sub-seasonal to seasonal*
598

599 Methodology and tools will be developed to interpret HYDROSOS data and information for
600 agricultural applications (including snow, ice, soil moisture, groundwater, irrigation, water
601 storage). Review of available and reliable methodologies to be used for specialized
602 applications of seasonal forecasts will be done as initial step to decide on further actions in
603 supporting of sectors such as inland navigation, energy, or health by specialized outlook
604 products.

605

606 *D.2 Effective dialogue between users and providers established*

607

608 Guidelines based on good practices on dialogues with users will assist Members to establish
609 consultation platforms and communication with users, including research on user
610 requirements and expectations, case studies of product and service development, marketing
611 strategies, and processes to support strategic service planning of NMHSs (including e.g.
612 catalogue of products and services).

613

614 *D.3 Strengthened capacity of NMHSs personnel in user driven product and services design 615 and delivery (in the field of support of food production and security)*

616

617 See C.5

618

619 *D.4 Water-food-energy nexus and ecosystem services are better understood and inform 620 water resources management*

621

622 Activities will facilitate discussion on the role of hydrology in providing the required data for
623 optimizing the management of water resources to accommodate the three sectors' needs;
624 through symposia, open panels, TED talks, or case studies on the water food energy nexus.

625

626 **On-going activities**

627 Food security is closely connected to water resources availability and droughts, therefore
628 again **Integrated drought management programme (IDMP)** might be seen as major
629 contributing activity in this regard together with continued implementation of the **WMO**
630 **Global Hydrological Status and Outlook System (HydroSOS)** and relevant activities in
631 the frame of **Capacity building in hydrology and water management** targeting
632 development and operation of food/production relevant services at Members' level.

633

634 **Assumptions and risks:**

635 We assume that integrated drought management is a priority at national level for Members.

636

637 Risks are in possible:

638

- 639 • Change in overall political and societal priorities e.g. due to COVID-19 pandemic
640 results in decreased involvement in water-related agenda
- 641 • COVID 19 pandemic is altering WMO modalities of work, with a potential impact on
642 efficiency due to teleworking and impossibility of face-to-face meetings.
- 643 • Lack of alignment with other activities in the field of Water (e.g. UNESCO-IHP)
644 leading to competition for attention of governments.

- 644
- 645
- 646
- 647
- 648
- 649
- In case of GDPFS, lack of candidates to become centers operating under GDPFS rules and development of centers outside the umbrella of GDPFS (including in private sector) that undermines the idea of GDPFS as well as lack of acceptance of the GDPFS hydrology structure by NHSs
 - Lack of financial resources for core activities of the Secretariat

650 **To be finalized based on consultations**

651

652 **2.5 ambition/goal: High-quality data supports science**

653 *Globally accepted and free accessible data*
654 *infrastructure is lacking – monitoring data from NHSs*
655 *and research is not brought together. Harald Köthe*
656 *and Stephan Dietrich, consultation on needs and gaps*
657

658 The interoperability between science and data generates knowledge and progress. The value
659 of data accessibility, usability and reliability has been proved to be a strong driver for the
660 science development.

661 Mandatory data availability policy has been established and enforced in some sectors, but
662 increased contribution is still needed to establishing common standards and policies for data
663 management and sharing, to support generation of high-quality hydrometeorological data
664 and corresponding information products and services for research and development.
665

666 **Outcome:** Increased discoverability, availability, and use of high-quality
667 hydrometeorological and hydrologic data for scientific analysis
668

669

670 **Metrics:** Success in this outcome will be measured by:

- 671 • Number of discharge time series with data available for 2021-2030 period that are
672 accessible via WMO infrastructure and programmes (such as WIS, WHOS, GRDC) for
673 scientific purposes on free and unrestricted basis.

674

675 **Needs and gaps**

676 To ensure production of quality data, concept of QMF-H was developed and promoted by the
677 WMO, however it is likely still not well understood or not considered to be a priority by all
678 Members. Materials and guides are not easily implementable (including language barrier) or
679 implementation cost is too high.

680 At the same time, variety of hydrological conditions and regimes is extreme, finding one fit-
681 all solution for hydrological observation standardization and quality control procedure is a
682 challenge. In addition, differences in development and capacities among members are great
683 – application of methods from developed countries might be too demanding for some
684 developing Members, while in opposite, too benevolent methods might not suite countries
685 with developed monitoring programmes.

686 Exchange of data for scientific community remains limited at global level, due to restricting
687 data policies of some Members, but also due to lack of flexible, easy to use technical
688 platform. In addition, research community requirements on data (and its characteristics) is
689 not always well defined and may differ from day-to-day operational needs.

690 Research institutes and operational agencies under certain conditions compete for resources
691 – both financial (funding) and human. It is usual that NHSs perform some research
692 activities, with increased competition of larger research teams, work at the NHSs might be
693 feared to degrade to routine operation only which would mean decreased motivation for
694 staff and decreased prestige for the institution. This competition might be overcome by
695 balanced partnership and mutual cooperation on applied research. Similarly, combination of
696 data from long-term in-situ observing networks with short research observation,
697 experimental data, and other sources of information (e.g. satellite) to 'one stock' is
698 opportunity for better cooperation towards shared goals.

699

700 **Outputs:**

701 *E.1 Methods for standard assessment of data quality developed*

702 Guidelines on assessment and flagging of hydrological data reflecting its quality will be
703 develop, including development of practical methods for such assessment. Continuous
704 process of revise and updating of Technical Regulation Vol. III will be initiated targeting in
705 particular the Annex on Hydrometry. Other hydrology related materials/documents will be
706 revised for QMF-H compliance.

707

708 *E.2 Quality assured hydrometeorological data by NHSs are generated through increased
709 compliance to the culture of Quality Management Framework - hydrology (QMF-H)¹*

710 Activities will support Members to achieve QMF compliance by development of generic data
711 production processes (schemes), metrics and internal guidelines for easy customization for
712 NMHSs. Training materials and e-learning on QMF will be produced, including basic field
713 safety manual/training course. Members will be encouraged to implement QMF by
714 information highlighting the benefits of QMF.

715

716 *E.3 Improved development and maintenance of technical platforms to support data
717 discovery and accessibility for exchange for research and science*

718

719 Integration of hydrological networks to relevant WMO platforms through implementation of
720 WHOS. Role of existing global datacenters will be redefined to better support needs of
721 Members in data sharing and joining WIS/WIGOS, including sharing of data from research
722 basins and projects by academia.

723

724 *E.4 Improved coordination on observing networks to fit the research purposes*

725

726 Based colloquium/conference on data for scientific purposes that would identify what and
727 how to measure to enhance scientific progress of hydrology - a concept paper for jointed
728 distributed hydrological laboratory will be developed for further consideration.

729

730 *E.5 Enhanced culture of research & development projects co-design and joint management
731 (operational hydrology and academia)*

732

733 See F.1

734

735 **On-going activities**

736 **Quality management framework – Hydrology** has been promoted as key principle to
737 ensure production of high quality and quality controlled data for various purposes including
738 research. As measurement technology developed, **Assessment of the performance of**

¹ Quality Management Framework - Hydrology goal is to provide strategy, advice, guidance and tools for the National Hydrological Services to attain quality, efficiency and effectiveness in their functioning. As such it provides documentation on approaches to Quality Management System (QMS) and guidance on its adoption and implementation by NHSs; documentation and guidance on management of NHSs; documentation on technical approaches for the provision of hydrological data, products and services; and development of training modules and materials.

739 **flow measurements** has become a major initiative to support National Hydrological
740 Services in correct and effective use of new equipment in everyday operation. It needs to
741 continue support hydrologist by guiding on methods of hydrometric measurements and its
742 quality assessment. At the same time a need for new possibilities of measuring data, where
743 conventional methods are not available or too expensive, was recognized. **The Global**
744 **Hydrometry Support Facility (HydroHub)** has been initiated in response helping
745 developing Members to increase number and reliability of observations. The **WMO**
746 **Hydrological Observation System (WHOS)** ensures hydrological data operation and
747 management in the frame of WIS/WIGOS with foreseen continuation of its implementation
748 (phase II).

749
750 **Assumptions and risks**

751
752 **To be finalized based on consultations**

753

754 **2.6 ambition/goal: Science provides a sound basis for operational**
755 **hydrology**

756
757 The responsibility for operational services needs to be based on the state of knowledge of
758 the water resources and the current and foreseeable pressures on them. The fundamental
759 research on the other hand needs to be tailored to user needs, in an applied research
760 approach. Earth system science in an integrated perspective broadens the hydrological
761 perspective and the advancement of hydrological science.

762
763 **Outcomes:**

- 764 • Reduced gap between research and operational hydrology applications; operational
765 hydrology uses improved understanding of Earth system science
- 766 • There is a greater understanding of how the hydrological system responds to
767 extreme conditions

768
769 **Metrics:** Success in this outcome will be measured by:

770 Number of WMO (co-)sponsored research programmes/projects that includes
771 implementation of operational hydrological applications at Members' level during 2021-
772 2030.

773
774 **Needs and gaps**

775 Gap between research and practice paradoxically increases. One of the reasons is that NHSs
776 are not always recognized as beneficiaries (clients) and users of research results. It points
777 to possible weak customer orientation of some research teams towards operational services,
778 and to limited understanding the production/value chain from meteorology/climatology to
779 hydrology/water management in case of research topics stretching over scientific domains.
780 Obviously, a separation of scientific and operational communities is recognized as a problem
781 that needs to be overcome by closer cooperation and twinning. It is agreed that
782 enhancement of operational hydrology demands for an interdisciplinary approach not
783 limiting the scope to hydrological sciences.

784 Among identified research needs for operational purposes, there is an urgent need for
785 inexpensive sensors and telemetry, cloud based platforms and free satellite data reception.
786 Satellite observation and other emerging types of data are a promising source of
787 information but demand for calibration and 'merging' with in-situ observation. It is also
788 recognized that the science of Earth system has developed significantly over last decades,
789 yet the transfer to practice lags behind in many parts of the World. Due to extreme dynamic
790 of research, it has become impossible for practitioners from NHSs to observe, research,
791 follow and use all relevant products and outputs. In addition of those operational products
792 available, few fits hydrological needs on resolution (basin scale), sets of parameters,
793 frequency of data, formats, etc. A big challenge for use of meteorological and climate data
794 for hydrological applications remains fact that without bias correction water balance might
795 be disturbed, but bias corrected data do not always keep the physical sense.

796
797 **Outputs:**

798 *F.1 Enhanced culture of research & development to operation projects co-design (by*
799 *operational hydrology and academia) - (Demonstration) projects are developed with*
800 *beneficiaries being National Meteorological and Hydrological Services*

801

802 Implementation of research strategy for hydrology in the frame of overall WMO research
803 programme will help closing research to operation gap (including close cooperation with
804 UNESCO-IHP and IAHS). It will be supported by developing a catalogue of case studies/best
805 practices for cooperation for direct enhancements of NHSs operations by
806 targeted/customized research and continuous updating of database of research needs from
807 NHSs as a project topics repository for scientist.

808

809 *F.2 Enhanced collaboration between hydrology and meteorology communities of practice,*
810 *including academia*

811

812 See B1.4 and B2.7

813

814 *F.3 Inventory of the compiled data and products from Earth systems science projects for*
815 *hydrological applications*

816

817 See B0.11, B1.7 and B2.2

818

819 *F.4 Improved Earth system models at high resolution for local and regional applications*

820

821 NHSs have the tools to assess and predict the current and future state of the water
822 resources. Information is available to fully integrate surface and groundwater resources to
823 improve earth system modelling and forecasting, in particular QPE and QPF.

824

825 *F.5 There is a greater understanding of how the hydrological system responds to extreme*
826 *conditions*

827

828 Tools and modules to assess and analyse uncertainty of extreme conditions are available.
829 Research community further develops uncertainty and scenario analysis that can be directly
830 used to design/manage infrastructure & water systems.

831

832 **On-going activities**

833 **Assessment of the performance of flow measurements** represents an example of
834 applied research transformation for the benefits of operational hydrology by evaluation
835 performance and uncertainties associated with new technologies for flow measurement. In a
836 broader scope **the Global Hydrometry Support Facility (HydroHub)** is intended to
837 stimulate applied science for operational hydrology through development of new methods,
838 instruments, and tools for practice. In the field of floods, several research demonstration
839 projects were developed within the frame of the **WMO FFI Flood Forecasting Initiative**.
840 However, in the field of hydrology, research belongs to responsibility of the UNESCO-IHP at
841 the UN level. Therefore cooperation and coordination of research activities would be
842 necessary with external partners including UNESCO-IHP and IAHS through Hydrological
843 Coordination Panel and Research Board.

844

845 **Assumptions and risks**

846

847 **To be finalized based on consultations**

848

849 **2.7 ambition/goal: We have a thorough knowledge of the water resources**
850 **of our world**

851 Collecting, managing and sharing data on water resources and uses, (all the key variables
852 associated with operational hydrology) are fundamental for a better understanding of
853 resources and developing appropriate water management solutions, informing the decision-
854 making process, from local to global scale.

855 Despite the advances in technology and policy, we are far from having comprehensive
856 information on the state of water management across the world, nor featuring major
857 characteristics, trends, constraints and prospective changes.

858 Regional analyses need to be supported by systematic, up-to-date and reliable information
859 on water and to serve as a reference for large-scale planning and predictive studies.

860

861 **Outcome:** Members implemented reliable water resources assessment systems to deliver
862 and share information on water resources availability

863

864 **Metrics:** Success in this outcome will be measured by:

- 865 • Number of Members providing their water resources assessment through HydroSOS,
866 or other WMO regional systems.

867

868 **Needs and gaps:**

869 Many Members, especially in the developing countries require investment and support to
870 build the skills, tools and infrastructure (hydrological and meteorological monitoring
871 networks; framework and IT infrastructure for data curation, archival and retrieval systems
872 and quality assurance) needed to enhance their NMHS's capacity to transform hydrological
873 and meteorological observations into actionable water resources information. That includes
874 investment in reporting framework (including use of common standards) for hydrological
875 status and outlooks information and human capacities to develop and operate it.

876 As a result of above mentioned, access to water resources assessment information for
877 general public and for advanced users with contextualization is missing. To develop it,
878 integration and coordination between climate and hydrology community of practice would be
879 necessary. Improved water, food, energy security and public safety requires due
880 consideration of the river basin scale, but at the moment, there's lack of methods for
881 blending high resolution datasets of streamflow, gauged rainfall, lake levels, soil moisture
882 and evaporative demand at hydrologic relevant scales.

883 What is missing at the moment seems to be a 'catalogue' of hydrological tools describing
884 capabilities and credible information on fit for purpose nature of the tools and investments
885 warranted by member states NHSs for their adoption and use. There's also a need for
886 capacity building in hydrological modelling technologies and prediction systems that focus
887 on resolving weather and climate to hydrology problem for empowering Member states to
888 develop decision support systems to manage water supply and demand pressures.

889 In some cases, NMHSs struggle to understand stakeholders' and users' needs due to limited
890 communication and cooperation (connection to) these communities. Water resources
891 management needs to be framed in well-developed planning processes at various levels and
892 well linked to assessment of its impacts and benefits.

893

894 **Outputs:**

895 *G.1 Current status/assessment of water resources is available at different spatial and*
896 *temporal scales and covers variability of products including e.g. snow, groundwater,*
897 *lakes, and reservoirs*
898

899 Increased and enhanced water resources assessment activities performed at national scale
900 will provide inputs to the HydroSOS at global scale. HydroSOS will be implemented in line
901 with implementation plan.
902

903 *G.2 WMO community informs high-level policy discussions at global scale*
904

905 Based on Concept note, format and specification of general hydrology advisory will be
906 developed and later implemented (including building support network/structure for
907 production for regular production.
908

909 *G.3 Data, products and model results, at adequate spatial and temporal resolutions, are*
910 *available for actionable planning and operations at the local scale*
911

912 WMO will develop a system of GDPFS centers that produce data and information specialized
913 to support water resources assessment of Members, based on their requirements. Members
914 will be provided with training materials and tools if needed to interpret GDPFS products for
915 national and local applications for WRM.
916

917
918 *G.4 Increased national capacities to collect water-related data and transform them to*
919 *useful/relevant products through capacity building (The staff of NMHSs understands*
920 *the societal impacts of water and water resources management plans and decisions,*
921 *the importance of water resources assessments for various stakeholders, and is well*
922 *informed on the technologies available for them to best carry out their tasks and are*
923 *expert in those that best suit their key applications)*
924

925 Compendium of societal, economic and ecologic relations/dependency on water/hydrological
926 cycle will be developed based on review of existing studies, synergising and collating
927 information. Community of practice for water resources assessment will support NMHSs
928 including support to apply available tools and products, helps in selection of proper
929 methodologies and tools for WRA by Members (including support to twinning projects
930 between Members targeting water resources assessment and water resources
931 management). Training curriculum for WRA will be developed as a part of capacity
932 development strategy of the WMO. Based on curricula, courses and training materials will be
933 developed. WRA 'manual' will be published.
934

935 **On-going activities**

936 Historically water resources have been considered at national or basin level mostly. **The**
937 **WMO Global Hydrological Status and Outlook System (HydroSOS)** is implemented as
938 critical activity in the field of assessment of water resources at global and regional levels. Its
939 implementation will be enabled by enhancement and implementation of **WHOS** and will be
940 supported by continued **Capacity building in hydrology and water management.**

941
942
943
944
945

Assumptions and risks

To be finalized based on consultations

946 **2.8 ambition/goal: Sustainable development is supported by hydrological**
947 **information**

948
949 The availability of hydrological information does support all water-dependent sectors for
950 optimal water resources management as well as for planning and adapting to transient
951 environmental conditions. Majority of goals of the UN sustainable development agenda have
952 connection to water, therefore hydrological information is important for monitoring and
953 assessment of SDGs.

954
955 **Outcome:** Hydrological information of adequate resolution, quality and timeliness is
956 available and being used for informed decisions on sustainable development at all scales.

957
958 **Metrics:** Success in this outcome will be measured by:

- 959 • Number of Members including hydrological aspects and water budget information to
960 their development plans at national level.
- 961 • Number of Members reporting on SDG using reliable hydrological data and indicators

962
963 **Needs and gaps:**

964 When speaking about sustainable development agenda, it seems that lack of awareness of
965 the central role of water in SDGs and need for integrated actions prevails in the community
966 of operational hydrologists. So far, there was no need for creation of variables that are
967 monitored by hydrological services for the purpose of international SDG monitoring. In some
968 countries, understandably, priorities are in delivering of flood and drought warnings and
969 developing capacities in these fields, while creation of information and products is second
970 order priority at the moment. If such variables are developed, we may face hesitation to
971 send data to be stored somewhere else for global purposes and back-up.

972
973 **Outputs:**

974
975 *H.1 Improved data policies, financing schemes, and enhanced political arrangements to*
976 *collect hydrologic data and derived products*

977
978 Implementation of resolution on data policy will be supported by development of the
979 reference network for hydrology and recognition mechanism of centennial station in
980 hydrology to highlight the importance of sustainable contribution.

981
982 *H.2 Intensified national, basin, transboundary and international cooperation and activities to*
983 *meet SDG*

984
985 Output will be delivered by supporting the building of national, basin and transboundary
986 partnerships for WATER SDGs by compilation of success stories. At global level, partnership
987 with FAO and UNESCO will be established to develop a plan for hydrological
988 data/information/products collection for support of the SDG. For that purpose, definition of
989 set of parameters to monitor and support sustainable development on a long-term scale is
990 foreseen.

991

992 *H.3 Basic tools to assist members are created, including an archive of relevant information,*
993 *tools for transforming data to information, and maintenance of essential*
994 *"treasury/heritage" variable to support SD*

995
996 Concept note/feasibility study will be developed to assess possibility to develop WMO
997 hydrology cloud for storage of essential data of Members for consideration of CG and
998 potential implementation. Sharing of data from recognized centennial/reference network will
999 be supported leading to implementation of GBON for hydrological domain. SW (or cloud
1000 solution) for computation of parameters for support of SDG, including its web presentation.

1001
1002 **On-going activities**

1003 The World Water Data Initiative aims to reply to needs of sustainable development
1004 implementation in the field of water/hydrology information. While concrete tools and
1005 activities targeting sustainable development has not been fully developed yet by the WMO
1006 community, obviously the **WMO Global Hydrological Status and Outlook System**
1007 **(HydroSOS)**

1008 Will be the central activity in this regard supported by **Hydrological data operation and**
1009 **management** infrastructure.

1010
1011 **Assumptions and risks**

1012
1013 **To be finalized based on consultations**

1014

1015 **2.9 ambition/goal: Water quality is known**

1016 *Without water quality information, the*
1017 *decisions made on the use of the water*
1018 *resource will be partial and biased.*

1019 José Alberto Zúñiga, consultation on needs and
1020 gaps
1021

1022 **Outcome:** (At national level) increased cooperation and water quality data exchange.
1023

1024 Water quality is integral part of the water cycle. The monitoring of surface and groundwater
1025 quality is a necessary condition for the basic requirements of society and ecosystems, and
1026 the possibility to adopt timely corrective solution whenever needed.
1027

1028 **Metrics:** Success in this outcome will be measured by:

1029 Number of Members running water quality monitoring programmes and performing water
1030 quality assessments.
1031

1032 **Needs and gaps:**

1033 The main gap in water quality assessment is limited awareness of society and politicians of
1034 the need for water quality assessment resulting to limited financial resources for this field
1035 and missing coordinated and integrated monitoring programme in water quality in some
1036 member countries. Water quality monitoring is technically and financially demanding and at
1037 many parts of the World it has not become a priority in situation of limited resources. This
1038 might be connected to missing or limited understanding of principles of Integrated water
1039 resources management and interconnection of all water related processes at decision
1040 making level as well at level of relevant institutions.

1041 It is often a different authority, other than Hydrological Service, that bears responsibility for
1042 water quality (and related health issues). In some cases, functional partnerships of
1043 responsible organizations at national/regional level has not been established yet. In the
1044 past, there's been a lack of impetus for majority of hydrological service to start their
1045 involvement in water quality monitoring resulting in limited coordination between quantity
1046 and quality monitoring networks and separate assessments of quality and quantity aspects
1047 of water.

1048 At WMO, water quality has not been considered relevant domain so far, mostly due to
1049 missing demand form Members' level – from National Hydrological Services. While basic
1050 cooperation with UNEP, UNESCO-IHP and WHO exists, limited knowledge
1051 of programmes and activities from outside of the WMO (like GEMS) to National Hydrological
1052 Services prevails. In addition, development projects are usually not designed as joint
1053 quantity-quality solving complex projects. A need to cooperate with existing water quality
1054 activities at global level, in particular with UNEP GEMS, is well recognized. At the same
1055 time, there are no internationally agreed standards for exchanging water quality sampling
1056 data and exchange of water quality data is limited – likely also due to various
1057 responsibilities at national scale in the field of water quality.
1058

1059 In consequence it seems that scarcity of WQ data, even in major water bodies (surface and
1060 underground), doesn't allow to perform environmental baseline studies required for
1061 Environmental Impact Assessment and Environmental Management Programmes of
1062 engineering projects etc. And finally, unavailability of water quality data limits applicability
1063 and enforcement of relevant environmental policies and regulations of industrial/domestic
1064 effluents.

1065 And it is a lack of water quality standards (limits) for ambient water quality that is seen to
1066 be limiting for effort of many member states. Similarly, more guidelines are demanded to
1067 help develop water quality monitoring programmes at national level differentiate among
1068 surveillance monitoring (for regulatory or enforcement purposes) with systematic
1069 monitoring of water quality (long term changes) nor with alarm systems for pollution
1070 accidents. All of these are important but serves different purposes and involve different
1071 stakeholders. The role of National Hydrological Service and the WMO seems to be most
1072 prominent in systematic monitoring of specific parameters. Finally, it is recognized that
1073 sediment load demands for specific attention, in particular with respect to reservoirs.
1074

1075 **Outputs:**

1076 *I.1 Partnership at UN level exists and promotes provision of WQ data from NHSs to existing*
1077 *information systems (such as GEMS, IIWQ, ISI)*

1078 Responsibility on Water Quality at UN level is shared between WMO, UNESCO and UNEP.
1079 Establishing WMO-UNEP-UNESCO partnership or coordination mechanism on water quality
1080 building on the World Water Quality Alliance is a key to enhance availability of water quality
1081 information at global level and increase the effectivity of development activities through a
1082 joint work plan. Existing systems (WHOS, GEMS, IIWQ) needs to be interconnected to share
1083 and exchange data in standardized formats and procedures.
1084

1085 *I.2 Increased NHSs involvement in co-production of water quality related data and products*
1086 *thanks to promotion of IWRM principles.*

1087 Not all NHSs holds responsibilities in the field of water quality currently, but water quality
1088 aspects are becoming more important in the frame of the SDGs and thus monitoring and
1089 assessment are being developed by Members. Activities aim to support building of
1090 partnerships for water quality at national and international basin scale, to support
1091 formulation of the National Water Quality Management Strategy, Action plans and
1092 Monitoring Programs including data policies. Based on identified needs water quality training
1093 materials will be developed.
1094

1095 *I.3 Increased joint water quantity and water quality assessment (monitoring and modelling)*
1096 *for operational management and for planning*

1097 Review of state of operational monitoring, modelling and assessment of water quality at
1098 Members and basin level and its systematic update will inform other activities on needs and
1099 gaps at Members level and will help to develop joint WMO-UNEP-UNESCO strategy to
1100 increase availability of water quality assessments from Members and on international
1101 basins. A concept paper for inclusion of water quality to HydroSOS will be developed for
1102 further consideration of WMO water community.
1103

1104 *I.4 Water quality aspects are included in country support activities/projects in the spirit of*
1105 *IWRM and in cooperation with other organizations*

1106 Water quality determines availability of water resources just as water quantity. Both needs
1107 to be considered adequately in development projects to ensure successful enhancement of
1108 Members abilities to manage water resources and achieve SDGs. Through the partnership
1109 with UNEP, UNESCO, UNDP and WB a definition of minimum requirements/checklist for
1110 water quality aspects to be included in country support activities will be developed and
1111 applied.
1112

1113 *I.5 Partnership at UN level delivers co-produced guidelines related to water quality*

1114 WMO-UNEP partnership will gather an expertise to develop consistent guidelines for water
1115 quality monitoring and assessment for the use of responsible authorities at national level.

1116 Most prominently to develop and update Technical Regulation Vol. III – hydrology Annex on
1117 water quality.

1118
1119 **On-going activities**

1120 Water quality has been underdeveloped domain among WMO operational hydrology
1121 activities so far. While it has been partly considered within **Quality management**
1122 **framework – Hydrology** documentation, it's obvious that most lot has to be done in
1123 **Capacity building in hydrology and water management, Hydrological data**
1124 **operation and management** needs to be accommodated to water quality information
1125 processing. There's a great potential to benefit from **the Global Hydrometry Support**
1126 **Facility (HydroHub)** infrastructure and mechanisms to help develop non-expensive water
1127 quality monitoring programmes in Members states where these are not in place yet.

1128
1129 **Assumptions and risks**

1130 Proposed activities and outputs 8.3, 8.2 and 8.4 are based on basic assumption that
1131 relevant partners (UNEP, UNESCO, WB) will joint WMO in these activities following same
1132 goals and providing adequate resources necessary. Additionally, there's assumption of
1133 increasing demand from Member on water quality related actions from WMO. In particular,
1134 that Members, with no systematic programmes for water quality monitoring and
1135 assessment, will aim to develop and maintain water quality monitoring as a priority and
1136 contribution to SDG (outputs to 8.1, 8.5 and 8.2).

1137
1138 Global pandemic of COVID-19 represents an eminent risks for achievement of all outputs.
1139 Post-pandemic economic situation might further limit development of relatively expensive
1140 measures in water quality due to decrease of resources available and potential shift in
1141 priorities at national and global level for recovery from the pandemic. Limited resources
1142 might limit both, a demand from Members, as well as capacities of UN system to react.
1143 Additional risk for 8.1, 8.5, 8.2 and 8.4 would be a lack of expertise mobilized for WMO from
1144 Members expert database to deliver on planned activities. Given the fact that water quality
1145 is not a common responsibility of NHSs, experts often stay outside the NMHSs and might be
1146 difficult to be approached and attracted to contribute.

1147
1148 **3) Partnership**

1149
1150 Successful achievement of the Long-Term Ambitions and implementation of enhanced
1151 services will require partnerships to:

- 1152 a) Foster collaboration for sustainable, improved, tailored and affordable hydrological
1153 services;
1154 b) Strengthen the capacities of National Hydrological and Hydrometeorological Services;
1155 c) Support regional and transboundary initiatives and approaches that optimize basin-
1156 wide water management, including hydrological data exchange;
1157 d) Improve the general understanding of the societal benefits of hydrological services;
1158 and
1159 e) Assist in responding to the requirements of international processes

1160
1161 **4) Way forward?**

1162
1163 **Monitoring and assessment of the Action plan implementation**

1164 Monitoring and assessment of the Action plan implementation will be done by the
1165 Hydrological Coordination Panel based on inputs and monitoring of progress of work plan of
1166 Technical Commissions, Research Board, Regional Associations and other implementing
1167 bodies and by assessment of defined milestones and success criteria for all activities,
1168 outputs and outcomes. Report on progress will be produced biannually for consideration of
1169 EC and Congress/Hydrological Assembly respectively.
1170

1171 **Review of the Action plan**

1172 Based on the monitoring and assessment, Hydrological Coordination Panel will develop in
1173 coordination with SERCOM, INFCOM, Research Board and Regional Associations an update
1174 of the Action plan and submit to Hydrological Assembly for endorsement and to adoption by
1175 regular Congress-19 (2023) and Congress-20 (2027).
